Shear horizontal waves in a nonlinear elastic layer overlying a rigid substratum

Dilek Demirkus* and Mevlut Teymur†‡

Abstract
In this work, the propagation of shear horizontal (SH) waves in a homogeneous, isotropic and compressible nonlinear hyper-elastic layer having finite thickness is studied. The upper surface of the layer is assumed to be free from traction and the lower boundary is rigidly fixed. These waves are dispersive like the Love waves. The problem is examined by a perturbation method that balances the nonlinearity and dispersion in the analysis. A nonlinear Schrödinger equation is derived describing the nonlinear self modulation of the waves. Then, the effect of nonlinear properties of the material on the propagation characteristics and on the existence of solitary waves are discussed.

Keywords: Dispersive nonlinear shear horizontal waves, Multiple scale method, Bright solitary waves, Dark solitary waves.

1. Introduction
Elastic waves propagating in an unbounded media are non-dispersive i.e. phase velocities of waves are constants. On the other hand, in wave guides such as rods, plates, layered half space, etc., the phase velocities of the waves depend on wave number, hence the waves are dispersive. Dispersive elastic waves have been studied extensively, because of their application in geophysics, nondestructive testing of materials, electronic signal processing devices, etc. (see, e.g. Ewing et al. [1], Love [2], Achenbach [3], Graf [4], Farnell [5], Maugin [6]).

In recent years, the effect of the nonlinear material parameters on the propagation characteristics of dispersive elastic waves has been the subject of numerous investigations

‡Corresponding Author.
for similar reasons mentioned above. By employing asymptotic perturbation methods
many problems related with the propagation of nonlinear dispersive waves are examined.
In these works, as a result of balance between nonlinearity and dispersion various nonliner-
ear evaluation equations such as Korteweg-DeVries (KdV) equation, modified Korteweg-
DeVries (mKdV) equation, nonlinear Schrödinger (NLS) equation, Boussinesq equation
etc. have been derived to elucidate the nonlinear wave motion asymptotically. Then
various aspects of the problems such as the stability of modulated wave, the existence
of solitary waves, etc. were discussed on the basis of these equations. For an extensive review
of most of these works we refer to Parker and Maugin [7], Maugin [8], Parker [9], Mayer
[10], Norris [11], Porubov [12]. Among the works on nonlinear dispersive elastic waves,
the investigations of nonlinear shear horizontal(SH) waves occupies an important place.
Below some of these works will be reviewed to relate the present work to them. In [13],
Bataille and Lund considered the propagation of nonlinear Love waves in a layered half
space covered by a thin linear elastic layer. A modified Boussinesq equation is derived by
an intuitive approach guided by physical arguments which accounts the dispersive nature
of Love waves and the nonlinearity. This equation has an approximate modulated solitary
wave (an envelope solitary wave) solution which provides mechanisms for localized en-
ergy propagation along the surface of the layered medium. The propagation of nonlinear
Love waves in a half space covered by a layer of uniform finite thickness having different
mechanical properties, is investigated by a perturbation method in [14] by Teymur. The
materials of the layer and the half space are both assumed to be homogeneous, isotropic
and compressible hyper-elastic. Then, it is shown that the nonlinear self modulation of
Love waves is governed asymptotically by an NLS equation. The coefficients of this NLS
equation are valid on all branches of the linear dispersion relation of Love waves for any
wave number. From the numerical evaluation of these coefficients for various material
parameters it has been observed that the stability of modulated waves, the existence of
envelope (bright) and dark solitary waves depend strongly on the nonlinear properties of
the layered media as well as the wave number. The problem is reconsidered by Maugin
and Hadouaj [15] where the nonlinear substrate covered by a linear thin elastic layer and
then by Teymur et al.[16] if the top layer is made of a thin nonlinear elastic material.
In [17], Ahmetolan and Teymur studied the propagation of nonlinear SH waves and the
formation of Love waves in a double layered plate each having finite thickness. In [18],
Ahmetolan and Teymur examined the propagation of nonlinear SH waves in a plate hav-
ing finite thickness and made of a generalized neo-Hookean material. An NLS equation
is derived which governs the nonlinear self modulation of waves asymptotically and the
effect of nonlinearity on the propagation characteristics is discussed. The propagation of
small but finite amplitude long SH waves in a double layered plate is examined in [25] by
Teymur. In that work by an asymptotic analysis, a modified KdV equation is derived
and then the dependence of various types of solitary wave solutions on the nonlinear
material parameters are discussed. The propagation of large amplitude Love waves in
a layered half-space made of different pre-stressed compressible neo-Hookean materials
(restricted Hadamard materials) is examined by Ferreira and Bokuenger [30] and an exact
solution of the problem is given. Later, the anti-plane shear motions coupled with an
in-plane motion for a Hadamard materials are considered by Pucci and Saccomandi [21].
The pure anti-plane motion may be sustained in a Hadamard material in the absence
of body forces. When the constitutive parameter $\beta$ is small, a perturbation analysis is
developed using this small parameter. Then this approach is also applied to the propaga-
tion of finite amplitude Love waves in a layered half space made of Hadamard materials.
And the solutions exhibiting a secondary in-plane motion caused by a principal anti-plane
motion are given.
In the present work, we consider the propagation SH waves in a homogeneous isotropic compressible nonlinear elastic finite layer deposited on a rigid substratum. The upper surface of the layer is assumed to be free from the stress. This problem may model some real world problem. A uniform layer of a nonlinear soil overlying a rigid bedrock is an example from soil dynamics (see for example[22]). Also a soft material layer overlying an almost rigid material is an another example from the signal processing applications (see for example [8] and [15]). The problem is examined by a perturbation method. By balancing the nonlinearity and dispersion in the analysis, an NLS equation is derived describing the nonlinear self modulation of SH waves. Then, the effect of nonlinearity on the propagation characteristics of waves and on the existence of solitary waves are discussed.

2. Formulation of the Problem

Let \((x_1, x_2, x_3)\) and \((X_1, X_2, X_3)\) be, respectively, the spatial and material coordinates of a point referred to the same rectangular Cartesian system of axes. Consider an elastic layer of uniform thickness \(h\), occupying the regions between the planes \(X_2 = 0\) and \(X_2 = h\) in the reference frame \(X_K\). It is assumed that the boundary \(X_2 = h\) is free of traction and the displacements are zero at the rigid boundary \(X_2 = 0\). Now, an SH wave described by the equations

\[
x_k = X_K \delta_{kK} + u_3(X_\Delta, t) \delta_{k3}
\]

is supposed to propagate along the \(X_1\)-axis in the layer, where \(u_3\) is the displacement of a particle in the \(X_3\)-direction, \(t\) is the time and \(\delta_{kK}\) is the Kronecker symbol. The summation convention on repeated indices is implied in (2.1) and in the sequel of this section, and Latin and Greek indices have respective ranges \((1, 2, 3)\) and \((1, 2)\). Since \(\det(\partial x_k/\partial X_K) = 1\); the deformation field defined by (2.1) is isochoric and the density \(\rho\) of the layer in motion remain constant, i.e. \(\rho = \rho_0 = \text{constant}\).

Let \(T_{KL}\) be the first Piola-Kirchoff stress tensor field accompanying the deformation field (2.1); in the absence of body forces, the equation of motion in the reference state take the following forms

\[
T_{\Delta\beta,\Delta} + T_{3\beta,3} = 0, \quad T_{\Delta3,\Delta} + T_{33,3} = \rho_0 \ddot{u}_3
\]

where subscripts preceded by a comma indicate partial differentiation with respect to coordinates \(X_K\) and an over dot represents the partial differentiation with respect to \(t\) [14].

The assumption of vanishing traction on the free surface of the layer imposes the boundary condition

\[
T_{2k} = 0 \quad \text{on} \quad X_2 = h,
\]

and on the rigid boundary

\[
u_3 = 0 \quad \text{on} \quad X_2 = 0.
\]

Let us now assume that the constituent material of the layer is nonlinear, homogeneous, isotropic and compressible hyper-elastic. Stress constitutive equations for such a material may be expressed as

\[
T_{kk} = (\partial \Sigma / \partial I_1) \delta_{LL} + 2 \partial \Sigma / \partial I_2 E_{LK} + 3 \partial \Sigma / \partial I_3 E_{LM} E_{MK} x_k, L
\]

where \(E_{KL} = (x_k, K x_k, L - \delta_{KL})/2\) is the Lagrangian strain tensor and \(\Sigma\) is the strain energy function (see e.g. Eringen and Suhubi [23]). For an isotropic material, \(\Sigma\) is an isotropic function of the invariants of \(E\) defined as

\[
I_1 = trE, \quad I_2 = trE^2, \quad I_3 = trE^3.
\]
For the deformation field (2.1), the invariants are found to be

\( I_1 = Q/2, \quad I_2 = Q(1 + Q/2)/2, \quad I_3 = Q^2(3 + Q)/8. \)

where

\( Q = Q(u_3) = u_{3,\Delta} u_{3,\Delta}. \)

The stress-strain relations (2.5) now read [14],

\[ T_{\Delta\beta} = \frac{\partial \Sigma}{\partial I_1} \delta_{\Delta\beta} + \left( \frac{\partial \Sigma}{\partial I_2} + \frac{3}{4} \left( 1 + Q \right) \frac{\partial \Sigma}{\partial I_3} \right) u_{3,\Omega} u_{3,\Delta} \delta_{\Delta\beta}, \quad T_{\Delta 3} = 2 \frac{\partial \Sigma}{\partial Q} u_{3,\Delta}, \]

\[ T_{3\alpha} = -u_{3,\Delta} T_{\Delta\alpha} + \delta_{\alpha\Delta} T_{33}, \quad T_{33} = \frac{\partial \Sigma}{\partial I_1} + \left( \frac{\partial \Sigma}{\partial I_2} + \frac{3}{4} \left( 1 + Q \right) \frac{\partial \Sigma}{\partial I_3} \right) Q. \]

Note that for a specific material \( \Sigma \) is a prescribed function of \( Q \) through the invariants (2.7). Hence the equations of motion (2.2) are three equations to be satisfied by a single function \( u_3 \). For any material defined by (2.5), if the first two equations in (2.2) are satisfied by a given solution of the third equation in (2.2), then the motion (2.1) can exist in the medium in the absence of body forces. This is only the case if \( \Sigma = \Sigma(I_1) \), i.e. if the medium is made of a generalized Neo-Hookean material (see e.g. Teymur [19] or in more detail Saccomandi and Ogden [24]). In general without any restriction on the constitutive relation (2.5) (or (2.9)), the system of equations (2.2) is not compatible so that the motion (2.1) cannot be maintained without body forces acting in the \( (X_1, X_2) \)-plane (see for details Carroll [25], Pucci and Saccomandi [26], Rogers et al. [27]). Therefore as \( \Sigma_3 \) is satisfied identically and the third equation becomes

\[ 2 \frac{\partial \Sigma}{\partial Q} u_{3,\Delta} \delta_{\Delta\alpha} = \rho_0 \ddot{u}_3. \]

It is seen from (2.9) that for such a material the strain energy function \( \Sigma \) must satisfy the following conditions

\[ \frac{\partial \Sigma}{\partial I_1} = 0, \quad \frac{\partial \Sigma}{\partial I_2} + \frac{3}{4} \left( 1 + Q \right) \frac{\partial \Sigma}{\partial I_3} = 0, \]

whenever the invariants are given by (2.7). We now employ the following fourth order polynomial expansion of \( \Sigma \) in terms of the strain invariants \( I_i \) to deduce approximate equations

\[ \Sigma = \alpha_1 I_1^2 + \alpha_2 I_2 + \alpha_3 I_3^2 + \alpha_4 I_1 I_3 + \alpha_5 I_3^4 + \alpha_6 I_3^4 + \alpha_7 I_3^4 I_2 + \alpha_8 I_1 I_3 + \alpha_9 I_2^3 \]

where \( \alpha_1 = \lambda/2, \alpha_2 = \mu \) are second order (\( \lambda \) and \( \mu \) are the usual Lamé constants), \( \alpha_3, \alpha_4, \alpha_5 \) are third order and \( \alpha_6, \alpha_7, \alpha_8, \alpha_9 \) are fourth-order elastic constants. The third order elastic constants related to the Murnaghan’s constants \( l, m, n \) as (see Norris [11])

\[ \alpha_3 = \frac{1}{3} \left( l - m + \frac{1}{2} n \right), \quad \alpha_4 = \left( m - \frac{1}{2} n \right), \quad \alpha_5 = \frac{n}{3}. \]

Then employing (2.12) in the stress-strain relation (2.9) and applying the restrictions on \( \Sigma \) defined in (2.11) we get

\[ T_{11} = T_{12} = T_{21} = T_{22} = T_{33} = 0, \]

\[ T_{\Delta 3} = \mu u_{3,\Delta} + (\alpha_3 + m/2) u_{3,\Delta} Q + O(Q^2), \]

and the equation (2.10) becomes

\[ \ddot{u}_3 - c^2 u_{3,\Delta\Delta} = n_T (u_{3,\Delta} Q)_\Delta + O(Q^2). \]
where

$$c_T^2 = \mu/\rho_0, \quad n_T = (a_0 + m/2)/\rho_0$$

Here, $c_T$ is the linear shear velocity and $n_T$ the nonlinear material constant which exhibit the nonlinear characteristics of the constituent material. When $n_T > 0$, the medium is hardening in shear, but if $n_T < 0$, then it is softening.

Hence, the SH wave motion (2.1) can be maintained in the restricted hyper-elastic material defined by (2.14) without body forces acting in the $(X_1, X_2)$– plane. Now, let $X = X_1, Y = X_2, Z = X_3$ and $u = u_3$. Then from (2.14) and(2.15) the following approximate governing equation and boundary conditions involving terms not higher than the third degree in the deformation gradients are written;

$$\frac{\partial^2 u}{\partial t^2} - c_T^2 \left( \frac{\partial^2 u}{\partial X^2} + \frac{\partial^2 u}{\partial Y^2} \right) = n_T \left[ \frac{\partial}{\partial X} \left( \frac{\partial u}{\partial X} Q(u) \right) + \frac{\partial}{\partial Y} \left( \frac{\partial u}{\partial Y} Q(u) \right) \right]$$

(2.18) \quad \frac{\partial u}{\partial Y} \left( 1 + \frac{n_T}{c_T^2} Q(u) \right) = 0 \quad \text{on} \quad Y = h,

(2.19) \quad u = 0 \quad \text{on} \quad Y = 0.

3. Asymptotic analysis of the nonlinear SH waves

In this work, how the slowly varying amplitude of a weakly nonlinear SH wave is modulated by nonlinear self interaction is investigated by a perturbation method. For this purpose, the method of the multiple scales is employed by introducing the following new independent variables

$$x_i = \varepsilon^i X, \quad t_i = \varepsilon^i t, \quad y = Y; \quad i = 0, 1, 2, \ldots$$

instead of $X, Y, t$ \cite{28}. Here $\varepsilon > 0$ is a small parameter which measures the weakness of the nonlinearity, \{x_0, t_0, y\} are fast variables describing the fast variations in the problem while \{x_1, x_2, \ldots, t_1, t_2, \ldots\} are slow variables describing the slow variations. Now, $u$ is considered to be a function of these new variables and it is expanded in the following asymptotic series in $\varepsilon$;

$$u = \sum_{n=1}^{\infty} \varepsilon^n u_n(x_0, x_1, x_2, \ldots, y, t_0, t_1, t_2, \ldots)$$

In this work we aimed to obtain first order uniformly valid asymptotic solution of the problem. Therefore in the following part we will assume the dependence of $u_n$ on the slow scales \{x_1, x_2, t_1, t_2\} only. If one studies the contribution of higher order terms then the third order, in the analysis the dependence on the slower scales \{x_3, \ldots, t_3, \ldots\} should also be considered as independent variables. Now, first writing the equation of motion (2.17), the boundary conditions (2.18) and (2.19) in terms of the new independent variables (3.1) and then employing the asymptotic expansion (3.2) in the resulting expressions and collecting the terms of like powers of in $\varepsilon$, we obtain a hierarchy of problems from which it is possible to determine $u_n$, successively. Up to third order in $\varepsilon$ these are given as follows;

$$O(\varepsilon):$$

(3.3) \quad \mathcal{L}u_1 \triangleq \frac{\partial^2 u_1}{\partial t_0^2} - c_T^2 \left( \frac{\partial^2 u_1}{\partial x_0^2} + \frac{\partial^2 u_1}{\partial y^2} \right) = 0,

(3.4) \quad \frac{\partial u_1}{\partial y} = 0 \quad \text{on} \quad y = h,

(3.5) \quad u_1 = 0 \quad \text{on} \quad y = 0.$
\( O(\varepsilon^2) : \)

\begin{align}
L_{u_2} &= 2 \left( c_T^2 \frac{\partial^2 u_1}{\partial x_0 \partial x_1} - \frac{\partial^2 u_1}{\partial t_0 \partial t_1} \right), \\
\frac{\partial u_2}{\partial y} &= 0 \quad \text{on} \quad y = h, \\
u_2 &= 0 \quad \text{on} \quad y = 0.
\end{align}

\( O(\varepsilon^3) : \)

\begin{align}
L_{u_3} &= 2 \left( c_T^2 \frac{\partial^2 u_2}{\partial x_0 \partial x_1} - \frac{\partial^2 u_2}{\partial t_0 \partial t_1} \right) + c_T^2 \left( \frac{\partial^2 u_1}{\partial x_0 \partial x_2} + 2 \frac{\partial^2 u_1}{\partial x_0 \partial x_1} - \frac{\partial^2 u_1}{\partial t_0 \partial t_2} - 2 \frac{\partial^2 u_1}{\partial t_0 \partial t_1} \right) \\
&\quad + n_T \left[ \frac{\partial}{\partial x_0} \left( \frac{\partial u_1}{\partial x_0} K(u_1) \right) + \frac{\partial}{\partial y} \left( \frac{\partial u_1}{\partial y} K(u_1) \right) \right] \\
\frac{\partial u_3}{\partial y} + \frac{n_T}{c_T} K(u_1) \frac{\partial u_1}{\partial y} &= 0 \quad \text{on} \quad y = h \\
u_3 &= 0 \quad \text{on} \quad y = 0
\end{align}

where

\[ K(u_1) = \left( \frac{\partial u_1}{\partial x_0} \right)^2 + \left( \frac{\partial u_1}{\partial y} \right)^2 \]

Note that the perturbation problems are linear in each step. Moreover the first order problem is simply the classical linear problem which was first investigated by Hudson [29]. Let us examine this problem. For the existence of an SH wave in the layer, the phase velocity of the wave must satisfy the inequality

\[ c > c_T \]

i.e. an SH wave having a phase velocity less than the linear shear wave velocity \( c_T \) of the medium does not propagate in the layer. We proceed by assuming that the above inequality is satisfied by the phase velocity of the SH wave. Then by using the separation of variables method, the solution of the governing equation (3.3) is found to be

\[ u_1 = \sum_{\ell=1}^{\infty} \left[ A_1(\ell)(x_1, x_2, t_1, t_2) e^{i k p y} + B_1(\ell)(x_1, x_2, t_1, t_2) e^{-i k p y} \right] e^{i \phi} + \text{c.c.} \]

where

\[ p = (c^2 / c_T^2 - 1)^{1/2}, \quad \phi = k x_0 - \omega t_0. \]

and \( A_1(\ell), B_1(\ell) \) are the first order amplitude functions of the slow variables, \( k \) is the wave number, \( \omega \) is the angular frequency, \( c = \omega / k \) is the phase velocity, and c.c. denotes the complex conjugate to the preceding terms. The substitution (3.14) into the boundary conditions (3.4) and (3.5) yields the following system of homogeneous linear equations for the first order amplitude functions;

\[ \textbf{W}_\ell \textbf{U}_1(\ell) = 0 \]

where

\[ \textbf{W}_\ell = \begin{bmatrix} i k p e^{i k p h} & -i k p e^{-i k p h} \\ 1 & 1 \end{bmatrix} \]

is the dispersion matrix and, \( \textbf{U}_1(\ell) \) are the first order amplitude vectors defined as

\[ \textbf{U}_1(\ell) = \begin{bmatrix} A_1(\ell) \\ B_1(\ell) \end{bmatrix} \].
Note that $\det W_1 = 0$ gives the dispersion relation of the linear SH waves [29]:

(3.19) \quad \cos(kph) = 0.

Hence

(3.20) \quad kph = (2n - 1) \frac{\pi}{2}, \quad \text{for} \quad n = 1, 2, ...

From here we write

(3.21) \quad \frac{\epsilon^2}{c_T^2} = 1 + \left[ \frac{(2n - 1)\pi}{2kh} \right]^2 \quad \text{or} \quad \omega^2 = k^2 c_T^2 \left[ 1 + \left[ \frac{(2n - 1)\pi}{2kh} \right]^2 \right]

where $n$ denotes the branches of the linear dispersion relation $\omega = \omega(k; n)$. Note that the dispersion relation (3.19) (or (3.21)) is the same of the dispersion relation for the antisymmetric motion of SH waves in an elastic isotropic plate with the thickness $2h$ occupying the region between the planes $Y = h$ and $Y = -h$. Therefore, the displacement field also corresponds to the antisymmetric deformation of the plate in the half part $[h, 0]$ (see [4] or [18]). Since the purpose of this paper is to examine the nonlinear self-modulation of waves centered around a wave number $k$, with corresponding frequency $\omega$. To exclude the harmonic-resonance in the analysis, we have to assume that

(3.22) \quad \det W_\ell \neq 0 \quad \text{for} \quad \ell \neq 1.

Then the solutions of the system of linear equations (3.16) are found to be

(3.23) \quad U^{(1)} = \mathcal{A}_1(x_1, x_2, t_1, t_2)R

and

(3.24) \quad U^{(\ell)} = 0 \quad \text{for} \quad \ell \geq 2

where $\mathcal{A}_1$ is a complex function of the slow variables describing slowly varying amplitude of wave modulation, and $R$ is a column vector satisfying

(3.25) \quad W_1 R = 0

Hence $R$ can be taken as

(3.26) \quad R = \begin{bmatrix} R_1 \\ R_2 \end{bmatrix} = \begin{bmatrix} 1 \\ e^{i k p h} \end{bmatrix}

and the first order solution is written explicitly as

(3.27) \quad u_1 = \mathcal{A}(x_1, x_2, t_1, t_2)[2i \sin(kpy)]e^{i\phi} + \text{c.c.}

Note that, the first order solution given in (3.27) and the solution of the linear problem are of the same form (see [29]). The only difference is that, in the linear problem $\mathcal{A}_1$ is a constant, but here it is a slowly varying function of the slow variables representing the nonlinear self-modulation of a wave train. To complete the first order solution of the nonlinear problem this function has to be determined. Therefore, to achieve this we proceed to examine the higher order perturbation problems. The use of the first order solution (3.27) in (3.6) of the second order perturbation problem yields

(3.28) \quad \mathcal{L} u_2 = 2i \left( \omega \frac{\partial \mathcal{A}_1}{\partial x_1} + kc_T^2 \frac{\partial \mathcal{A}_1}{\partial x_1} \right) \left( e^{ikpy} + e^{ikp(2h - y)} \right) e^{i\phi} + \text{c.c.}

We now decompose the solution of (3.28) as

(3.29) \quad u_2 = \tilde{u}_2 + \bar{u}_2
where $\bar{u}_2$ is the particular solution of non-homogeneous equation (3.28) and $\tilde{u}_2$ denotes the solution of the following problem obtained from the second order problem by the use of the decomposition (3.29)

(3.30) $\mathcal{L}\bar{u}_2 = 0$

(3.31) $y = 0; \quad \bar{u}_2 = -\tilde{u}_2$

(3.32) $y = h; \quad \frac{\partial \bar{u}_2}{\partial y} = -\frac{\partial \tilde{u}_2}{\partial y}$

The particular solution $\bar{u}_2$ of the non-homogeneous equation (3.28) is found by the method of undetermined coefficient as

(3.33) $\bar{u}_2 = \frac{1}{kpc_f^2} \left( \frac{\partial A_1}{\partial t_1} + kc_f^2 \frac{\partial A_1}{\partial x_1} \right) \left( -e^{ikpy} + e^{ikp(y-h)} \right) ye^{i\phi} + c.c.$

The solution $\tilde{u}_2$ of the homogeneous equation (3.30), as in the first order problem, can be written as follows

(3.34) $\tilde{u}_2 = \sum_{\ell=1}^{\infty} \left[ A_2^{(\ell)}(x_1, x_2, t_1, t_2)c^{ikp} + B_2^{(\ell)}(x_1, x_2, t_1, t_2)e^{-ikp} \right] e^{i\ell\phi} + c.c.$

where $A_2^{(\ell)}$ and $B_2^{(\ell)}$ are the second order amplitude functions of the slow variables. Then the use of this solution together with the particular solution (3.33) in the boundary conditions (3.32) and (3.33), yields the following linear system of equations to determine $A_2^{(\ell)}$ and $B_2^{(\ell)}$

(3.35) $W_{\ell}U_2^{(\ell)} = b_2^{(\ell)}$

where

(3.36) $U_2^{(\ell)} = \begin{bmatrix} A_2^{(\ell)} \\ B_2^{(\ell)} \end{bmatrix}$

and the vectors $b_2^{(\ell)}$ are found as

(3.37) $b_2^{(1)} = \begin{bmatrix} 2ihc^2 \left( \frac{\partial A_1}{\partial t_1} + kc_f^2 \frac{\partial A_1}{\partial x_1} \right) e^{ikph} \end{bmatrix}$

and

(3.38) $b_2^{(\ell)} = 0 \quad$ for $\ell \geq 2$

A little algebra reveals that, $b_2^{(1)}$ can be put into the following form

(3.39) $b_2^{(1)} = -i \left( \frac{\partial A_1}{\partial t_1} \frac{\partial W_1}{\partial \omega} - \frac{\partial A_1}{\partial x_1} \frac{\partial W_1}{\partial k} \right) R$

For $\ell \neq 1$, since it is assumed that $\det W_{\ell} \neq 0$ for $\ell \neq 1$, the solutions of (3.35) are

(3.40) $U_2^{(\ell)} \equiv 0, \quad \ell \neq 1,$

but, since $\det W_1 = 0$ and $b_2^{(1)} \neq 0$, in order that the linear system of equations (3.35) solvable for $U_2^{(1)}$, the compatibility condition

(3.41) $L b_2^{(1)} = 0$

must be satisfied, where $L$ is a row vector defined by

(3.42) $LW_1 = 0$

and an $L$ can be taken as

(3.43) $L = [L_1, L_2] = \begin{bmatrix} i, kpc^{ikph} \end{bmatrix}$
The compatibility condition (3.41) then yields
\[ \frac{\partial \phi_1}{\partial t_1} + V_g \frac{\partial \phi_1}{\partial x_1} = 0 \]
where \( V_g \) is the group velocity of the waves defined as
\[ V_g = \frac{d \omega}{dk} = -\left( \frac{\partial L}{\partial k} \right) \frac{1}{\left( \frac{\partial L}{\partial \omega} \right)} \]
This equation state that the first order amplitude \( \phi_1 \) remains constant in a frame of reference moving with the group velocity \( V_g \), i.e. \( \phi_1 = \phi_1(x_1 - V_g t_1, x_2, t_2) \). Then the solution of the equation (3.35) for \( \ell = 1 \) can be written as
\[ \phi_2 = \phi_2(x_1, x_2, t_1, t_2) \]
where the complex function \( \phi_2 \) is the second order amplitude and is a function of slow variables, and it remains arbitrary in this order. It can be calculated in higher-order problems when necessary. But, since this work is centered around the propagation of weakly non-linear waves it is aimed to obtain just uniformly valid first order solution. To obtain the first order solution, \( \phi_2 \) need not to be calculated explicitly, the determination of \( \phi_1 \) will be sufficient and it will be done at the third order problem. Note that, if we assume that \( \phi_2 \) depends on \( x_1 \) and \( t_1 \) through the combination \( x_1 - V_g t_1 \) as \( \phi_1 \), we can absorb it into \( \phi_1 \) since it is proportional to \( e^{i\omega} \) as \( \phi_1 \). Therefore in the following calculations we omit \( \phi_2 \). Now the substitution of the first and second order solutions into the third order equation (3.9) yields
\[ L u_3 = [(\mathcal{E}_1 + \mathcal{E}_2) e^{ikpy} + (\mathcal{E}_3 + \mathcal{E}_4) e^{-ikpy} + \mathcal{E}_5 e^{3ikpy} + \mathcal{E}_6 e^{-3ikpy}] e^{i\omega} + \text{c.c. terms in } (e^{\pm 3i\omega}) \]
(3.47)
where
\[ \mathcal{E}_1 = 2i(\omega \frac{\partial \phi_1}{\partial x_2} + kc_1 \frac{\partial \phi_1}{\partial x_2} + c_1^2 \frac{\partial^2 \phi_1}{\partial x_1^2} + \frac{\partial^2 \phi_1}{\partial x_1^2} - n_T k^4(9p^4 + 2p^2 + 9)\phi_1|\phi_1|^2, \]
\[ \mathcal{E}_2 = (-2i/kpc_2^2)(\omega \frac{\partial^2 \phi_1}{\partial t_1^2} + 2\omega kc_2 \frac{\partial^2 \phi_1}{\partial t_1 \partial x_1} + k^2 c_2^2 \frac{\partial^2 \phi_1}{\partial x_1^2}), \]
\[ \mathcal{E}_3 = c_1 e^{2ikhp}, \]
\[ \mathcal{E}_4 = -c_2 e^{2ikhp}, \]
\[ \mathcal{E}_5 = n_T k^4(9p^4 - 2p^2 - 3) e^{2ikhp} \phi_1 |\phi_1|^2, \]
\[ \mathcal{E}_6 = n_T k^4(9p^4 - 2p^2 - 3) e^{2ikhp} \phi_1 |\phi_1|^2. \]
(3.48)
Now, as in the second order problem we decompose \( u_3 \) as
\[ u_3 = \tilde{u}_3 + \bar{u}_3 \]
where \( \tilde{u}_3 \) denotes the particular solution of the equation (3.47) and \( \bar{u}_3 \) denotes the solution of the following problem
\[ L \tilde{u}_3 = 0 \]
(3.50)
\[ \tilde{u}_3 = -\bar{u}_3 \quad \text{on} \quad y = 0, \quad \tilde{u}_3 = \frac{\partial \bar{u}_3}{\partial y} = -\frac{n_T}{c_2^2} \mathcal{K}(u_1 |\partial u_1/\partial y|) \quad \text{on} \quad y = h. \]
(3.52)
The particular solution \( \tilde{u}_3 \) of the equation (3.47) can be expressed as a sum of linearly independent terms of the form
\[ \tilde{u}_3 = f_3^{(1)}(x_1, x_2, y, t_1, t_2) e^{i\omega} + f_3^{(3)}(x_1, x_2, y, t_1, t_2) e^{3i\omega} + \text{c.c.}, \]
(3.53)
where the terms \( f_3^{(1)} \) and \( f_3^{(3)} \) represent the self interaction and the third harmonic interaction of the waves, respectively. In this work since only the self interaction is considered, in the sequel the explicit form of the term \( f_3^{(3)} \) will not be required. Therefore, only \( f_3^{(1)} \)
will be calculated and this solution is obtained by the method of undetermined coefficient as

\[(3.54)\]
\[f_3^{(1)} = (D_1 + D_2 y) ye^{ikp \phi} + (D_3 + D_4 y) ye^{-ikp \phi} + D_5 e^{3ikp \phi} + D_6 e^{-3ikp \phi}\]

where

\[D_1 = i \mu c_4 kpc_7^2, \quad D_2 = i \mu c_2 kpc_7^2, \quad D_3 = -i \mu c_3 kpc_7^2, \quad D_4 = -i \mu c_4 kpc_7^2,\]
\[D_5 = \mu c_4 / 8kpc_7^2, \quad D_6 = \mu c_6 / 8kpc_7^2.\]

The problem posed for \(U_3\) can be treated as in the second order problem. The solution of the homogeneous equation (3.50) therefore can be written as

\[(3.55)\]
\[u_3 = \sum_{\ell=1}^{\infty} \left[ A_{3}(x, t_1, t_2) e^{ikp \phi} + B_{3}(x, t_1, t_2) e^{-ikp \phi} \right] e^{i\phi} + c.c.\]

where \(A_3^{(\ell)}\) and \(B_3^{(\ell)}\) are the third order slowly varying amplitude functions. Then the use of this solution together with the solutions \(u_1, u_2, u_3\) in the boundary conditions (3.51)-(3.52) yields the following linear system of equations to determine \(A_3^{(\ell)}\) and \(B_3^{(\ell)}\):

\[(3.57)\]
\[W_1 U_3^{(1)} = b_3^{(1)}\]

where \(b_3^{(1)} \neq 0, b_3^{(3)} \neq 0, \quad \text{and} \quad b_3^{(\ell)} = 0 \quad \text{for all} \quad \ell \neq 1, 3.\)

A lengthy but straightforward calculation discloses that \(b_3^{(1)}\) can be expressed as in the following form

\[(3.58)\]
\[b_3^{(1)} = -i \left( \frac{\partial W_1}{\partial \omega} \frac{\partial \phi_1}{\partial \omega} - \frac{\partial W_1}{\partial k} \frac{\partial \phi_1}{\partial x_2} \right) R + \frac{1}{2} \left( \frac{\partial^2 W_1}{\partial \omega^2} \frac{\partial^2 \phi_1}{\partial t^2_1} - 2 \frac{\partial^2 W_1}{\partial \omega \partial k} \frac{\partial \phi_1}{\partial x_1 t_1} + \frac{\partial^2 W_1}{\partial k^2} \frac{\partial \phi_1}{\partial x^2_1} \right) R + \left( \frac{\partial W_1}{\partial \omega} \frac{\partial^2 \phi_1}{\partial x_1^2} - \frac{\partial W_3}{\partial \omega} \frac{\partial \phi_1}{\partial x_1 t_1} \right) \left( \frac{\partial R}{\partial k} + V_3 \frac{\partial R}{\partial \omega} \right) + F|\phi_1|^2 \phi_1\]

where the components of the vector \(F\) are found to be

\[(3.59)\]
\[F_1 = -i \left[ \frac{nT^4 k^4 h}{c^2} \left( 9p^4 + 2p^2 + 9 \right) \sin(kph) \right], \quad F_2 = 0\]

The explicit form of the vector \(b_3^{(3)}\) is not given here, since it represents the third harmonic interactions and therefore in the sequel it will not be required. For \(\ell = 1\), (3.57) is an inhomogeneous equation and since \(\det W_1 = 0\), in order that this equation be solvable for \(U_3^{(1)}\) the following compatibility condition

\[(3.60)\]
\[L_3 b_3^{(1)} = 0\]

must be satisfied. For \(\ell = 3\), (3.57) is an inhomogeneous equation, but since it is assumed that \(\det W_3 \neq 0\) then the solution of (3.57) for this case is written as

\[(3.61)\]
\[U_3^{(3)} = W_3^{-1} b_3^{(3)}\]

When \(\ell \neq 1, 3\), (3.57) is a homogeneous equation and since \(\det W_\ell \neq 0\) for \(\ell \neq 1\) by assumption, then the solutions are

\[(3.62)\]
\[U_3^{(\ell)} = 0\]
An attempt will not be made towards obtaining the third order solutions explicitly since there will be no need for their explicit forms. The analysis will be continued by the examination of the solvability condition (3.61) to be satisfied at this order. This condition yields the following equations for $A_1$;

\begin{equation}
(3.64) \quad i \left( \frac{\partial \psi_1}{\partial t} + V_g \frac{\partial \psi_1}{\partial x} \right) + \tilde{\Gamma} \frac{\partial^2 \psi_1}{\partial x^2} + \tilde{\Delta} |\psi_1|^2 \psi_1 = 0
\end{equation}

where

\begin{equation}
(3.65) \quad \tilde{\Gamma} = \frac{1}{2} \frac{dV_g}{dk} = \frac{1}{2} \frac{d^2 \omega}{dk^2}, \quad \tilde{\Delta} = -\mathbf{L} \cdot \mathbf{F} / \left( \mathbf{L} \frac{\partial W_1}{\partial \omega} \mathbf{R} \right)
\end{equation}

In terms of the following non-dimensional variables and constants

\begin{equation}
(3.66) \quad \tau = \omega t_2, \quad \xi = k(x_1 - V_g t_1), \quad \alpha = k \alpha_1, \quad \Gamma = k^2 \tilde{\Gamma} / \omega, \quad \Delta = \tilde{\Delta} / \omega k^2
\end{equation}

this equation can be rewritten in the standard NLS equation form as

\begin{equation}
(3.67) \quad i \frac{\partial \alpha}{\partial \tau} + \Gamma \frac{\partial^2 \alpha}{\partial \xi^2} + \Delta |\alpha|^2 \alpha = 0
\end{equation}

Thus, once a solution for $\alpha$ is derived from (3.67) for a given initial value of the form

\begin{equation}
(3.68) \quad \alpha(\xi, 0) = \alpha_0(\xi)
\end{equation}

then the first order solution $u_1$ can be constructed by (3.27). Hence our task is completed.

4. Concluding remarks

We now examine the coefficients $\Gamma$ and $\Delta$ of the NLS equation obtained in this work, so that solutions of this equation are effected strongly by the sign of the product $\Gamma \Delta$.

From (3.65) and (3.66) it is found that

\begin{equation}
(4.1) \quad \Gamma \Delta = -n_T \frac{\rho c_T^4}{4c_T^6} (9p^4 + 2p^2 + 9)
\end{equation}

Since

\begin{equation}
(4.2) \quad \frac{\rho c_T^4}{4c_T^6} (9p^4 + 2p^2 + 9) > 0
\end{equation}

for all phase velocities $c > c_T$, then it is seen that if $n_T < 0$, i.e. if the layer is made of a softening material, then $\Gamma \Delta > 0$ for all phase velocities $c > c_T$. But if $n_T > 0$, i.e if the layer is made of a hardening material, then $\Gamma \Delta < 0$ for all phase velocities $c > c_T$. The variation of $C, V_g, \Gamma, \Delta$, and $\Gamma \Delta$ with the non-dimensional wave number $K = kh$ for the first three branches of the dispersion relation (3.21) are calculated and they are plotted in Fig(1), Fig(2), and Fig(3) respectively.

The NLS equation (3.67), as in this work, asymptotically describes the self modulation of the monochromatic plane waves in a nonlinear dispersive medium[30, 31]. It is also well known that the criterion whether $\Gamma \Delta > 0$ or $\Gamma \Delta < 0$ is important in determining how a given initial data will evolve for long times for the asymptotic wave field governed by the NLS equation. An initial disturbance vanishing as $|\xi| \rightarrow \infty$ tends to become a series of envelope solitary waves if $\Gamma \Delta > 0$, while it evolves into decaying oscillations if $\Gamma \Delta < 0$. On the other hand for disturbances that tend to a uniform state at infinity the envelope dark solitons exist for $\Gamma \Delta < 0$ [30, 31]. The behavior of the traveling wave solutions of the NLS equation of the form

\begin{equation}
(4.3) \quad \alpha(\xi, \tau) = \phi(\eta) e^{i(K\xi - \Omega \tau)}, \quad \eta = \xi - V_0 \tau, \quad V_0 = \text{constant}
\end{equation}
also depend on the sign of $\Gamma \Delta$. For $\Gamma \Delta > 0$, if $\phi \to 0$ and $d\phi/d\eta \to 0$ as $|\eta| \to \infty$ the solution for $\phi$ is
\begin{equation}
\phi(\eta) = \phi_0 \mathrm{sech}([\Delta/2\Gamma]^{1/2} \phi_0 \eta], \quad V_0 = 2K\Gamma
\end{equation}
where $(\Gamma K^2 - \Omega)/\Delta \phi_0^2 = 1/2$. This solution is known as envelope soliton or bright soliton [30, 31, 32]. When $\Gamma \Delta < 0$ and $(\Gamma K^2 - \Omega)/\Delta \phi_0^2 = 1$, if $\phi \to \phi_0$ and $d\phi/d\eta \to 0$ as $|\eta| \to \infty$, the solution for $\phi$ is
\begin{equation}
\phi(\eta) = \phi_0 \tanh[(-\Delta/2\Gamma)^{1/2} \phi_0 \eta], \quad V_0 = 2K\Gamma
\end{equation}
which represents the propagation of a phase jump [30, 31, 32]. Also, when $\Gamma \Delta < 0$ there are no solutions of the NLS equation (3.67) corresponding to the envelope soliton solution (4.5) of the case $\Gamma \Delta > 0$. However, a solution of the form
\begin{equation}
\phi(\xi, \tau) = \phi_0 e^{i[\Delta/2\Gamma \phi_0^2 \tau - F(\eta)]}
\end{equation}
which tends to the uniform solution $\phi_0 e^{i[\Delta/2\Gamma \phi_0^2 \tau]}$ as $|\eta| \to \infty$ exists, where
\begin{equation}
\phi_0^2 = \phi_0^2(1 - \sin^2 B \sec h^2 \psi), \quad F = \arctan(\tan B \tanh \psi)
\end{equation}
In (4.8) $B$ is a constant, $\psi$ and $V_0$ are given as
\begin{equation}
\psi = (-\Gamma \Delta/2)^{1/2} \phi_0 \eta \sin B, \quad V_0 = \pm 2^{-3/2}(-\Gamma \Delta)^{1/2} \phi_0
\end{equation}
This solution is known as dark soliton and it has all the usual soliton features [32]. The NLS equation (3.67) has also plane wave solutions whether $\Gamma \Delta > 0$ or $\Gamma \Delta < 0$. Hence, by considering the above given short review about the effect of the sign of $\Gamma \Delta$ on the properties of the solution of an NLS equation, we conclude that when the layer is made of a softening material, since $\Gamma \Delta > 0$ for all $kh > 0$ in this case, the envelope solitary SH waves will exist and propagate in such a medium. But, when the plate is made of a hardening material since $\Gamma \Delta < 0$ for all $kh > 0$ in this case, then only the dark solitary SH waves will exist in such a layer. The modulated envelope solitary waves (4.4) existing in a softening elastic layer may provide mechanisms for an efficient energy propagation along the free surface of the layer. Several investigator have shown that the shear stress is a nonlinear function of the strain in certain soils and $n_T < 0$, that is the response of the soil is softening in shear (see e.g. [33] and references given there). Therefore, when we consider a finite soil layer deposited on a rigid bedrock and showing this behavior under dynamic loading; one can observe the existence of an envelope soliton. An experimental result about the observation of solitons in soil mechanics was reported in [34] by Dimitriu.
